I. INTRODUCTION

The scheduling of events in any organization is a dynamic process which can require a manager's constant attention. Aboard U.S. Navy ships, the Operations Officer schedules and coordinates events such as underway periods, inspections and exercises. The command's schedule is developed following the guidance of superiors in the chain of command. This process is complicated and changes usually occur with very short notice at all levels in the chain of command.

The process at a shipboard level is normally manual. That is, most schedules are written on paper or cardboard. As changes occur, these schedules are manually corrected. This process is extremely slow, tedious and can lead to serious errors. Since this process is manual, many schedulers delay making the necessary updates or fail to make them at all. In the end, the ship's crew suffers because they are not kept properly informed of changes, which can lead to frustration and low morale. One improvement to the scheduling process could be to automate. For instance, by eliminating the need to search through manuals for current information, a scheduler could be more efficient and effective.

Argos is an ongoing research project at the Naval Postgraduate School. Its goal is to automate many of the manual activities on U.S. Navy ships and eventually make them less dependent on paper. All of the Argos applications feature a friendly graphical user interface which supports text and, to some extent, sound. Thus, anyone can quickly become proficient with Argos, whether a computer beginner or expert.

The Argos Scheduling Module was developed using the Hypercard scripting language which is now available as part of Macintosh system software.¹ Some work has been done to develop an application on personal computers using Microsoft Diskette Operating System (MS-DOS); however, most of the applications developed have been on Macintosh computers.² The need for an automated scheduling aid is great. Factors which can control a ship's schedule are numerous and changes occur constantly. The purpose of this thesis is to demonstrate the feasibility of a scheduling tool that can be used to automate and simplify the manual procedures which are in use today.

¹Macintosh and Hypercard are registered trademarks of Apple Computer, Inc.

²Microsoft and MS-DOS are registered trademarks of Microsoft Corporation.

This thesis is organized as follows: Chapter II discusses the scheduling process as it currently exists. Hardware constraints are presented in Chapter III. Chapter IV discusses the design and use of the scheduling prototype. Chapter V discusses the benefits of automating the scheduling process and conclusions and recommendations for follow on thesis work are presented in Chapter VI. Hypercard scripts of the major functions of the prototype are contained in the appendix.

II. BACKGROUND

An accurate schedule of events is critical to any organization. For U.S. Navy ships a schedule is the foundation upon which all other activities build. For example, maintenance personnel must have up to date knowledge of underway periods to facilitate the scheduling and accomplishing of preventive maintenance on major pieces of machinery which will affect main propulsion. Some activities require assistance from other commands or units, such as a crane which is used to remove a radar or other antenna from the ship's mast. Additionally, personnel must know when underway periods and inspections are scheduled in order to plan personal items, such as extended travel requiring leave.

A ship's Supply Officer determines how much money will be needed to support any special activities based upon upcoming events such as port visits. A ship's expenses depend upon whether the ship will moor to a pier or whether it will anchor out in a harbor as determined in the schedule. Perhaps one of the most important aspects of knowing a ship's schedule involves personnel training. Although simulators and trainers are available for many different watch stations, most personnel qualifications on a

ship require performing specific activities while the ship is underway. Several qualifications must be completed within time limits. Surface Warfare officer qualifications must be obtained within a reasonable period of time aboard ship or one could be dismissed from the Navy. If personnel can look at a list of events and determine when underway times are scheduled, then training times can be allocated to ensure all qualifications are achieved. This is especially critical when several people are competing for the same qualification. Finally, there are teams which must be trained. For example, several fire fighting teams must be qualified. The teams are comprised of members from every department on board a ship and training requires the personnel to be off the ship for two to three days. This evolution must be scheduled and promulgated well in advance so the impact of personnel shortages can be properly handled.

In spite of its importance, the scheduling process as it exists on most U.S. Navy ships today is prone to error and confusion. Each individual ship develops a schedule following a general outline issued from its squadron. Each squadron coordinates the activities of ten to fifteen ships. The squadron coordinates its scheduling up through the chain of command. Generally, about once every three months a ship will receive new guidelines from its squadron listing events which must be accomplished. Major underway periods are

already scheduled in these guidelines but other events can be scheduled by the ship. This task is most often performed by the Operations Officer, usually a senior lieutenant. Commonly, the process is completely manual and consists of listing events on a big piece of paper or cardboard. As changes occur, new schedules are made or old schedules are erased and annotated to reflect current information. Copies of these schedules are then made and distributed throughout the ship. Copies may be of poor quality either because of poor handwriting or faulty copiers. The end result is that many people cannot read or understand these schedules which leads to frustration and dissatisfaction.

The manual process described above has many inherent disadvantages including the following:

- the scheduler must search several instructions and manuals to determine event periodicity and event prerequisites.
- if old schedules are lost or destroyed, the formulation of new schedules is extremely error prone.
- because the process is manual, the extra instructions and old schedules add weight to a ship which negatively affects stability and fuel efficiency.
- the time consuming nature of these tasks is a deterrent to making changes in a timely manner. Sometimes it is impossible to keep up with changes as they occur. Such is often the case when a ship is underway and schedules can change every hour.
- since the process is so confusing usually one person performs all the necessary functions. Again, due to

routine personnel turnover, a new scheduler must familiarize himself with all of the procedures and manuals.

One way to improve the scheduling process is to automate activities which are now done by hand. Of particular importance is the elimination of searching various sources for information about each event. The application must be an improvement over current methods and must be designed with a ship's space and weight limitations in mind. Finally, the development and implementation of this application must be cost effective. [Ref. 1:pp. 5-6]

Throughout the development of the Argos Scheduling Module, these considerations were used as guidelines. Ultimately, with the help of this application, the Operations Officer could have an assistant perform some of the scheduling functions and conduct periodic checks to ensure completeness and accuracy. This would allow more than one person to have detailed knowledge about the process which would alleviate some of the problems that are caused by personnel turnover.

III. OPERATIONAL REQUIREMENTS

The purpose of this thesis is to develop a prototype for automation of a ship's scheduling process. The Argos Scheduling Module can enhance the performance of a ship. The purpose of this chapter is to define the hardware features necessary to make this system easy to learn and use.

The computer must be a platform that can support graphics and sound and must be small enough to fit aboard a ship with limited space [Ref. 1:p. 7]. It must also be rugged enough to withstand the rocking and vibration common to a shipboard environment. The speed at which this computer must perform is critical for some of the Argos applications. Finally, price is always a factor when considering any new system. Because of the advances made in the computer industry, a powerful computer system can be purchased for a very reasonable price.

There are several choices of computer hardware that can be selected to support the Argos Scheduling Module. Most of the applications for the Argos project to date have been developed on Macintosh computers utilizing the Hypercard programming language. There are, however, existing software packages that can be used to develop similar applications on

IBM compatible computers which use Microsoft Disk Operating System (MS-DOS) .

All Macintosh computers are able to support sound and are capable of being connected to a network if the appropriate software is installed. Any Macintosh computer that uses System 7 operating system automatically has the appropriate networking software installed. For Macintoshes without System 7 operating system, the networking software must be purchased separately. Usually the ability to support sound and to connect to a network are not part of the initial purchase of an IBM compatible computer. These capabilities require the purchase of additional computer cards which raises the final price of a system. These are important factors which must be considered. Although the sound and network features will make the initial purchase price higher, it is cheaper to buy them installed than it is to buy them later. [Ref. 1:pp. 7-8]

Since the acceptance and success of an application largely depends upon its user interface, an adequate monitor for the computer system is an important consideration. Monitors come in various shapes and sizes and can either be black and white or color. Over the last few years, monitors have become quite inexpensive. High resolution color monitors can be purchased for approximately \$500. A complete Macintosh computer system with a color monitor

operating at speeds ranging from 16MHZ to 33MHZ can be purchased for approximately \$3000. [Ref. 1:pp. 7-9]

The Hypercard language is a logical software tool because it supports prototyping. Prototyping can be defined as a working application that can be created quickly [Ref. 2]. The purpose of the prototype is to allow users to evaluate a computer application or system prior to its final implementation. Thus the prototype development should be inexpensive and flexible. Because Hypercard fulfills all of these requirements it was chosen for this and previous Argos projects.

The development of an application in Hypercard requires the use of one or more stacks. A Hypercard stack is a homogeneous collection of information. Each stack consists of several cards. A card can contain text or graphics and a new card can be added as more information is accumulated. A text field is used to write text on a card. Finally, buttons are used in cards and stacks to allow the user to operate. For example, a user can click his mouse on a button and go to a different card or to a different stack. Another use of a button could be to play sound or musical tunes. The possibilities for a button in any application are numerous. [Ref. 3:pp. 27-35]

In the Argos Scheduling Module, there are six stacks. When users open a stack for the first time, they will notice that the size of every card in the stack is nine inches.

This was designed to allow the application to be run on the earlier versions of Macintosh computers which have smaller screens. On newer computers with larger monitors, the card may not fill the entire screen. The card size can be adjusted accordingly, depending upon screen size and the amount of RAM available to Hypercard [Ref. 3:p. 106]. It is best to leave the card size at nine inches so the application can be used on any size monitor. When the size of a card is adjusted, some of the buttons and graphics may appear slightly offset from their original position. In these instances each item must be repositioned separately.

The six stacks of the Argos Scheduling Module and their cards, fields, and buttons perform many of the functions necessary for the scheduling process. The information required for scheduling, such as event periodicities and prerequisites, are also stored in these stacks. Some of the information is stored in fields which are visible to the user. Other information, such as the amount of fuel burned per day for a particular ship's class is hidden from the user and only brought into view as necessary. Finally, there is information in fields that is completely hidden but accessed by an application. No matter what type of field is used, it is important to realize that these fields are a type of database for any application developed in Hypercard.

Hypercard is used for prototyping because it provides the capability to store and manipulate information on a

limited basis. It is not intended to be used in the final production system. Research into using a relational database in the Argos project is ongoing. In a fully operational system, a database management software (DBMS) would be used. A DBMS permits users to create, maintain and extract information from the database.

A major distinction between Hypercard and database management software exists and must be explained. Hypercard lets a user move to other stacks to view or retrieve information as needed. One benefit of DBMS is its ability to generate reports. DBMS can also perform various functions on the output or send it to a printer. Hypercard is not designed for generating reports but is optimized for quickly looking through existing cards in search of desired information. The links between cards or stacks that are established in Hypercard are not rigid or finite and can be changed as new information is added. [Ref. 3:pp. 8-9]

IV. SYSTEM PROTOTYPE

A. DESIGN

Four stacks representing different ship classes were developed. In each of these, there are five cards which are used to collect information about each ship within these classes. The following is a description of each of these cards within the four stacks.

The first card welcomes the user to the Argos Scheduling Module and is the only card of its type in this project (Figure 1). The second card introduces the user to the types of ships which can be scheduled (Figure 2). Each silhouette represents a ship's class that is handled by this application [Ref. 4:p. 33]. Each ship is actually a transparent button which will lead the user to a different stack, each designed for one or two classes of ships.

As in Figure 2, there are six buttons which appear on every card in the four ship stacks. Two of these buttons are arrows which are located at the top of each card. The arrow which points to the right is used to advance the user one card in that direction. The arrow which points to the left performs the same action in a backward direction. On the bottom right of every card are four buttons, all of which utilize sound [Ref. 4:p 33]. These buttons are called

Figure 1
Scheduling Welcome Screen

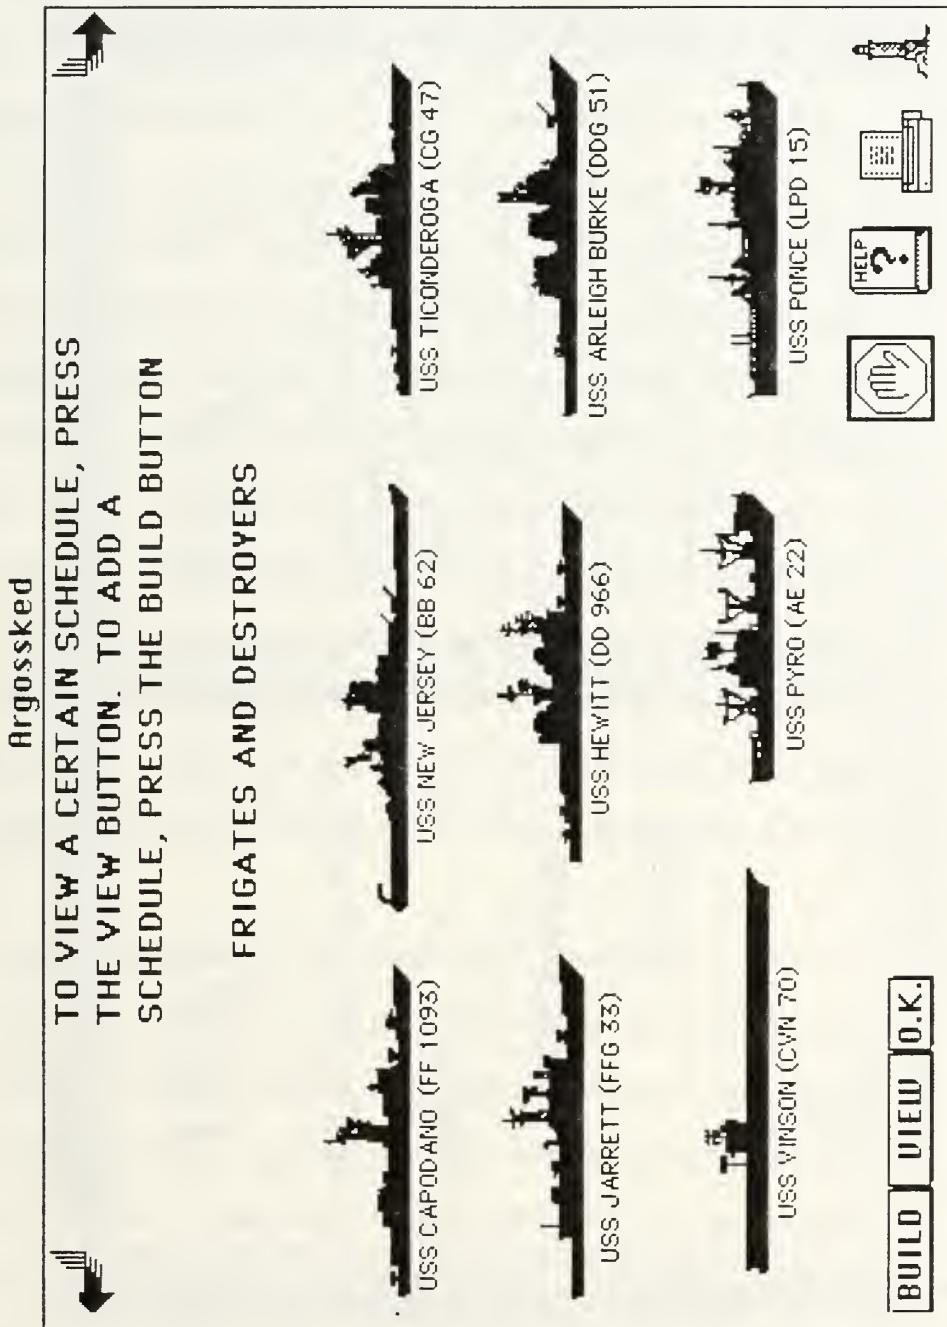

Figure 2
Ship Silhouettes

icons. An icon is a graphic image that can be used on screen displays [Ref. 5:p. 565]. Sound was installed in these buttons by using a stack called TALK TO ME! written by James L. Paul [Ref. 6]. The stack TALK TO ME! uses XCMDS which are compiled routines written in a language other than Hypercard which can do something that Hypercard cannot: in this case create sound [Ref. 7]. The first button, which looks like an open palm, is used to quit this application and Hypercard. The second button will enable a HELP stack, which provides a brief description of the design of this project and how to use the buttons. One card of this stack is shown in Figure 3. [Ref. 4:p. 134] The next button looks like a printer and is used to print out the card being viewed. The last button resembles a lighthouse and removes the user from this application but does not quit Hypercard. The sound alerts the user that these buttons perform special functions.

Moving to the next card the user will see six text fields called scrolling fields (Figure 4). By clicking the mouse on one of the arrows along the right edge of these fields additional information can be seen. In the first text field there is a list of inspections and events. Some of these are marked with an asterisk to signify there are special circumstances to be considered when scheduling them. By clicking the mouse on the EVENT button the user will see another field in which inspection prerequisites are

Figure 4
List of Inspections and Events

listed (Figure 5) [Ref. 8]. The asterisk ensures an inspection or event is properly scheduled. The second purpose of this card is to activate the computation of when each inspection or event can be scheduled. These dates are computed using the periodicity listed [Ref. 8]. Of course, the date that an inspection or event will actually be completed may vary but these computed dates provide guidelines for the scheduler. The third important function performed by this card is to compute any event not completed within the required periodicities. This information is vital because a ship must maintain a certain level of training and readiness at all times in order to complete upcoming operations. The text in the fields labeled EVENT and PERIODICITY cannot be erased or modified by certain users. These fields have a property called locked text [Ref. 3:p. 143]. This feature can only be activated or deactivated by someone with the proper authority and user level [Ref. 3:p. 25]. This was designed to ensure the integrity of the scheduling information.

The next card contains text fields which hold the current and next schedules, listed in chronological order (Figure 6). A third text field holds the events of a specific quarter of either the current or next schedules, listed in chronological order. These fields were designed to provide the scheduler the ability to view a list of

Figure 6
Current and Next Schedules

several events at a glance which facilitates long range planning.

The function of the next card is to compute fuel consumption (Figure 7). The DBSR button displays different classes of ships and their respective daily burn rate for fuel (Figure 8) [Ref. 9]. The first text field contains a list of employment terms and their respective fuel ratios. Both the field which holds daily burn rates and the field which holds employment terms are locked text. The purpose of this card is to provide a scheduler with a computation of the amount of fuel required for specific events. For example, the total amount required for a certain month or quarter can be computed based on upcoming events. The user is also provided with the number of barrels which can be used on a daily basis while underway. This feature allows either underway or inport refuelings to be scheduled in advance.

The final card that will be used for every ship is the Personnel Tempo Reporting Card (Figure 9). This card activates the computation of days personnel spend in homeport versus the number of days spent away from homeport. This is done each quarter and the quarterly point total is added to a cumulative point total in order to monitor trends. This trend is also displayed on this card. Finally, the scheduler can then enter the recovery date in the appropriate text field. The recovery date is defined as

the date when a unit will meet personnel tempo minimum standards. The minimum is defined by deployment length and turn around ratio (TAR). TAR is the ratio between the number of months a unit spends between deployments and the length of the last deployment. [Ref. 10]

The SCHEDULES stack is where the final schedule for a ship is printed out using a calendar (Figure 10 and Figure 11). The calendars are taken from a stack called STACK TEMPLATES which comes as a part of Hypercard. All stacks for the different types of ships were designed the same. Thus, users will see the same buttons throughout, which cuts down on the amount of time required to learn this application. Although the scheduling stack is different, schedulers should quickly learn how to use it effectively. The scheduling stack is really the end product; a useful schedule is produced. The other stacks act as worksheets. The scheduler inputs data in other stacks and that data is organized and displayed in the SCHEDULES stack so the user can quickly scan a schedule and base decisions on it. Thus the overall objective of making scheduling easier and more effective has been achieved.

B. DESCRIPTION

The easiest way to begin using the Argos Scheduling Module is to double click the mouse on the stack named

Figure 11
Example Schedule

Argosked. This action will enable the user to see the first card of this stack (Figure 1), which slowly dissolves to the second. The second card contains rectangular buttons which allow the user to perform scheduling actions. Every button in this application which is rectangular has a shadow visual effect. This is done to distinguish these buttons from some of the text fields, which are also rectangular.

The first button which can be used is the BUILD button. When the user clicks the mouse on this button, a box will appear that will require input from the user. This box is called a dialog box, and is used throughout this project. The first dialog box asks the user to input what type of ship will be added to the stack (e.g., FFG, CG, etc.). Next, the user is asked to input the number of a specific type of ship which is currently scheduled. Finally, the user will input the name of the ship. Once this is done, four cards will be added to the end of the stack. The user can then add appropriate information on each card. This function was designed so any number of ships can be added to each stack. (Hypercard has a 512 megabyte stack size limit, however, this is far more than will ever be needed in this project [Ref. 3:p. 129].) The VIEW button is positioned next to the BUILD button and is used to view the information about a ship already scheduled. A dialog box will prompt the user to input the type of ship to be viewed. The use of the BUILD button and the VIEW button cause text fields to

appear. The O.K. button is used to hide these fields. The contents of these fields will remain intact and can be brought into view again by using the BUILD or VIEW buttons.

The next card in each of the ship stacks contains several rectangular buttons (Figure 4). By depressing the EVENT button, the scheduler will see a text field in which inspection prerequisites are listed (Figure 5). The asterisk beside some of the events ensures an event is properly scheduled. The NEXT button is used to compute the next date each event can be scheduled based on the periodicities listed. Finally, the scheduler can view which events were not accomplished by depressing the OVERDUE button.

There are five buttons remaining on this card which perform important functions. The NEXT SKED button sorts the events in the NEXT field in chronological order and then lists these events in the NEXT SKED text field on the third card in the ship stacks (Figure 6). The CURRENT SKED button performs the same function on the events listed in the CURRENT field and then lists those events in the CURRENT SKED text field on the third card. The RESKED button allows the user to reschedule an event. The scheduler inputs the name of the event that must be rescheduled and the application will find that event. The user can then put in a new date.

Moving to the next card (Figure 6), the user will see the current and next schedules listed in chronological order. A certain event can be quickly located by depressing the FIND EVENT button. The VIEW QUARTER button is used to view an entire quarter of either the current or next schedule, in chronological order. The SCHEDULES button located in the lower left hand part of the screen is extremely important. This button will activate the SCHEDULES stack where the events for a ship are actually scheduled.

The computation of fuel consumption is activated by the next card (Figure 7). By depressing the DBSR button, the user will see a list of ship classes and their respective fuel burn rates (Figure 8). Clicking the mouse on the appropriate ship class will cause the appropriate burn rate to appear on this card. To start the process of computing a ship's fuel requirement the mouse is moved to the appropriate employment term and then depressed. A dialog box appears that prompts the scheduler to input the number of days spent underway for this specific event or task. After all terms have been selected, the FUEL REQ'T button will compute the total amount of fuel required in barrels and also the daily quota for days spent underway. Finally, the RESET button located at the bottom of the card must be depressed at the beginning of each new session. This

ensures that text is entered correctly into text fields each time fuel consumption is computed.

The final card in the ship stacks is the Personnel Tempo Reporting Card (Figure 9). The BEGIN button will present a dialog box requesting input for the number of days spent in homeport for a particular quarter. Then, the number of days in the quarter for which the perstempo is being figured is input. The quarterly point total will then be computed and listed. A negative number indicates more days were spent away from homeport than in homeport. A positive number indicates more time spent in homeport vice away from homeport and zero indicates an equal number of days spent in homeport and away from homeport. The CUMULATIVE P/T button calculates cumulative perstempo points and then displays the trend from the previous quarter as improving, declining or steady.

The first card of the SCHEDULES stack contains a card field which holds a list of the ships currently scheduled (Figure 10). The VIEW button allows the user to view the schedule of one of the ships currently scheduled. The QUIT button quits this application and Hypercard. Every other card in the SCHEDULES stack contains six buttons (Figure 11). On each of these, the COPY button is used to create a blank calendar which will be placed at the end of the stack. The most important button on each of these cards is the SCHEDULE button. This button creates the schedule for a

particular ship in the form of a calendar. The DATE button is used to put the correct month and year on the calendar. The DAYS button is used to label the days for a particular month. The QUIT button is used to quit this application and Hypercard. Finally, the RETURN button will move the user back into the ship stacks to the exact card which was originally being used.

In the HELP stack, the RETURN button is the main button which is used (Figure 3). Again, this button will return the user to the exact card which was originally being worked on in one of the ship stacks. This button also utilizes sound. The only other functional buttons in this stack are the arrow icons, which are used to move either forward or backward.

V. BENEFITS OF THE DEVELOPED PROTOTYPE

The Argos Scheduling Module offers many benefits to the users. The most important benefit is that the ship's scheduling process can be improved by automating the process. A small number of examples has been used in this prototype; however, a fully developed system could schedule nearly all of the ship's required activities. There may always be conflicts that cannot be automatically scheduled and perhaps they will be solved manually. Also, as stated earlier, a schedule is advisory. There are several factors involved in ship's scheduling which simply cannot be controlled. For example, a ship may suffer a machinery casualty just prior to getting underway which can delay departure. These situations will always exist, regardless of the scheduling method used. However, an automated scheduling system is beneficial by allowing fewer errors.

One benefit discovered while developing this project is the amount of time that can be saved by automating some of the scheduling process. The elimination of manually searching publications and instructions for information has been achieved in this project. In a fully developed system using a relational database, the elimination of the manual searching will save the user much time. Also, as

demonstrated in the SCHEDULES stack, past schedules can be maintained in an organized manner and reproduced on a moment's notice. The manual process wastes time when operators or schedulers try to locate and understand old schedules.

Another benefit of the Argos Scheduling Module is the standard appearance or format of the final schedules. The manual process allows each scheduler to use many different methods to list activities. As mentioned earlier, timelines drawn on cardboard or paper are some of the more common forms. As changes occur, old schedules are erased or written over. After several changes, these schedules are difficult to read and understand. However, schedules that are produced on a computer in a uniform manner will be much easier to update, read and understand. Also, if one standard method of displaying schedules is approved, the amount of time required to train new personnel will greatly decrease. This is crucial given the constant turnover of personnel.

One of the most important features that had to be considered when designing this project was how the Argos Scheduling Module would work with the other projects already completed. In order for the entire Argos project to be effective, the separate modules must be integrated to offer the greatest benefit to ships. One earlier module completed in the Argos project was designed around the maintenance of

a gas turbine engine. One function of that application was to assist a maintenance man in identifying and ordering a faulty part. Pages from the appropriate technical manuals were available to the user and the application completed most of the paperwork needed to order parts. The Argos Scheduling Module could be used in this case to determine the consequences of a needed part not being locally available. If a few computers were networked together, the maintenance man could look at the current schedule to determine the next underway period. He could then determine if upcoming commitments might be in jeopardy. This can be accomplished by simply placing a button in the maintenance application that will transfer the user to a stack containing a current schedule. Supply personnel could also have access to the same schedules and, based on the availability and location of a needed part, recommend further action, such as a casualty report.

Some of the other projects developed for Argos involve training. In this case, a benefit the Argos Scheduling Module offers if integrated is the ability to determine a ship's upcoming events so training can be scheduled accordingly. For instance, one application allows users to practice the steps required to control flooding due to underwater hull damage. If a ship is scheduled to go to Guantanamo Bay, Cuba, for refresher training, this training

application can be utilized to help personnel train and improve their skills.

There are benefits offered by integrating the scheduling module with the existing application that schedules preventive maintenance checks. Almost every piece of equipment on board U.S. Navy ships has one or more maintenance checks that must be performed within a certain periodicity (e.g., daily, weekly, monthly). Several of these checks require the equipment to be tagged out of service, that is, the equipment cannot be used until the maintenance is completed. On certain equipment this can affect the entire ship. For example, radar, communications, or other electronic equipment can suffer degraded performance because one of the air conditioning units is tagged out for maintenance. This could certainly be the case if a ship were operating in the Caribbean or the Middle East. However, if the preventive maintenance application is integrated with the scheduling application, a schedule would be readily available to all concerned. Thus, this maintenance could be scheduled at a time that would least affect ongoing operations. Alternatively, a maintenance man could check when the next in port period is and perhaps delay maintenance until then. Ideally, current schedules would be reviewed prior to formulating a maintenance plan in order to avoid rescheduling.

The Argos Scheduling Module can be integrated with existing projects to greatly benefit users in performing their daily tasks. As future projects are designed, this scheduling application should reveal many more uses.

VI. CONCLUSIONS

The development of this scheduling prototype in the Hypercard environment demonstrated the usefulness of a fully operational scheduling tool in which schedules can be quickly and accurately produced. These schedules are easy to read and understand and can be changed as operational requirements dictate. The need to search through numerous publications and instructions can be greatly decreased or perhaps eliminated.

An automated scheduling system can also help a scheduler become better at his job. For instance, in Figure 5 those events with prerequisites are marked with an asterisk and the necessary information is provided. This feature should alert a scheduler to these prerequisites at all times. An ability to easily calculate fuel requirements (Figure 7) allows a ship's Operations Officer to analyze his schedule in order to perform the most tasks given a certain amount of fuel.

Although one microcomputer could run all of the applications developed, several computers networked together would be more effective. This way, several members of the crew could have access to scheduling information. As mentioned earlier, schedules are usually posted in well

traveled areas of the ship, but it would be useful if certain people (e.g., each division officer or senior enlisted in each division) could have access to the SCHEDULES stack. This can be accomplished by giving the stack a certain password which can be changed as often as necessary to ensure security (REF. 3:p. 110). In addition, the Operations Officer could prepare a schedule which could then be reviewed by the Commanding Officer (CO) on his computer. The CO could then use several of the functions (fuel requirements, event prerequisites) to verify accuracy. This could be accomplished without a formal meeting which saves everyone time. Also, the CO can perform his review without having to search through all of the applicable manuals.

Although the Argos Scheduling Module has proven successful in several areas, there are features which can be improved. One of these features involves the rescheduling of events. If an event is rescheduled, all of the prerequisites must also be rescheduled. In the prototype, the user must reschedule each prerequisite separately. Relationships between events and prerequisites were not defined or programmed. One improvement would be to design the system so the prerequisites are rescheduled automatically. Another useful feature which could be added would be an automatic calculation of the fuel requirements for a ship given the activities that are scheduled. In the

prototype, this is accomplished using a separate card but the capability to automatically calculate fuel requirements based on a current schedule would be very useful.

As the Navy continues to respond to downsizing efforts and budget reductions as a result of events around the world, ships may spend more time in port. One way to overcome some of the problems associated with this situation is to take advantage of every underway opportunity to maximize training. This will require a schedule which is accurate and easy to modify in order to exploit any and all opportunities. The Argos Scheduling Module can provide these capabilities. It is an application that should help any ship take advantage of available resources in order to maintain a high degree of readiness.
